LiDAR Fundamentals

LiDAR, Light Detection And Ranging, is a remote sensing technique that uses a pulsating laser sensor to scan the surface. The reflected light pulses are detected by instruments that record the location of each return pulse in three dimensions. After processing, LiDAR point cloud data provide a detailed 3-D elevation model of the landscape.

LiDAR Collection Platforms

Fixed Wing

Rotary

Terrestrial

Mobile

LiDAR Fundamentals

- When the individual returns are viewed as a 3-D model, the result is an all returns LiDAR point cloud.
- The individual returns of a LiDAR point cloud appear to float at various levels, from the highest elevations (shown here in red) successively down to the lowest elevations, which are typically ground returns (shown here in blue).
- The point cloud data are interpreted by an analyst using specialized algorithms and classified into standardized categories according to the ASPRS LAS Data Exchange Format Standard established in 2003, *e.g.* Class 2=Ground.
- “A majority of LiDAR point cloud data describe vegetation and structures, not the ground surface .”The Oregon Geological Surveys’ analysis of ~20 billion pulses show that only 14% of the pulses produced returns from the ground surface.

Project Deliverables

- Raw, boresighted LiDAR (organized by flight line)
 - Classified, georeferenced, tiled LiDAR (LAS) data
 - Digital Elevation Model - DEM
 - Linear / polygonal breaklines (hydro-enforcement)
 - Digital Terrain Model – DTM
 - Elevation contours (topography)
 - Tile Scheme
 - Control Report
 - Project Metadata (FGDC-compliant)
 - Project Summary Report
- The LAS file format is an open, public file format for the interchange of 3D point cloud data between users (as defined by ASPRS)
 - Developed by ASPRS in conjunction with LiDAR vendors and industry members of the ASPRS Standards Committee

LiDAR Status

The U.S. Interagency Elevation Inventory is an online comprehensive, nationwide listing of known high-accuracy topographic data, including topographic and bathymetric LiDAR, as well as IfSAR. The USIEI is a collaborative effort between NOAA and the U.S. Geological Survey, with contributions from the Federal Emergency Management Agency...it is updated annually.

Illinois Height Modernization: LiDAR Derivatives

Data Products

Datasets in ArcGrid format are available for selected Illinois counties. The original, classified LiDAR data point cloud has been processed to create a digital terrain model (DTM) and a digital surface model (DSM) for each county. Additionally, each county zip file contains an associated shaded relief model, or 'hillshade', an ArcGIS v.10.1 .mxd file, and also ArcGrid pyramid files and statistics to facilitate display and analysis. Visit the [Illinois LiDAR Data](#) page to access originally contracted data deliverables (bare earth, contours, DAT, DGN, LAS, and TIN).

Product Definitions

DSM: all returns

Processing all returns in the classified point cloud that represent both the ground surface and aboveground features (buildings, roadways and overpasses, vegetation, etc.) produces a DSM. A DSM is commonly referred to as the 'First Returns' reflective surface model.

DTM: ground returns with hydrologic breaklines

When only the ground returns in a classified point cloud are used, the resulting hydro-flattened grid of bare-earth elevations is a DTM. Also, lake surfaces are smoothed and stream courses are conditioned for downhill flow using breakline data. This subset of the processed returns from the airborne laser sensor represent the ground surface and is commonly referred to as the 'Bare Earth' point cloud.

DEM: ground returns without hydrologic breaklines

When hydro-flattening is not imposed during processing of the ground returns, either because of missing or insufficient breakline data, the resulting Bare Earth elevation grid is classified as a DEM.

expected = LiDAR has been acquired but not yet delivered; derivative data products will be produced.
 by request = derivative data available upon request. Please submit Help Request Form.
 not acquired = LiDAR not acquired or planned
 contact county = distribution is available only through county; contact information available from ISGS.
 (-s) = digital surface model not yet available.

Metadata

Generalized metadata has been produced for each county DTM/DEM and DSM derivative data product, which can be accessed by clicking on a selected grid file using ArcCatalog. Be certain you have first selected on the ArcCatalog toolbar the 'FGDC CSDGM Metadata' option under Customize > ArcCatalog Options > Metadata. Please refer to the [Readme file](#) within each county ZIP download file for additional distribution information.
